OBJECTIVES

Background: Paediatric hypertension is increasing and has been associated with obesity and insulin resistance. Recently, cortisol/cortisone ratio and the metalloproteinase 9 (MMP-9), which is a marker of vascular remodeling, have been syndicated as new risk factors associated with hypertension.

Objective and hypotheses: To analyze the association between pediatric hypertension with clinical, biochemical, inflammation, and vascular remodeling biomarkers

METHODS

- A cross sectional study was designed. We selected 320 subjects (4 to 16 years old, female 49.4%), anthropometric parameters, serum aldosterone (SA), plasma renin activity (PRA), cortisol, cortisone, HOMA-IR, hsCRP, adiponectin, IL-6, TNF-α, PAI-1, MMP-2 and MMP-9 activities were measured.

- We calculated SA/PRA ratio (ARR > 10, as screening of hyperaldosteronism) and serum cortisol/cortisone ratio as 11β-HSD2 activity estimation.

- The systolic and diastolic blood pressure indexes were calculated (SBP= observed / 50th percentile blood pressure).

RESULTS

- According the Fourth Report of Task Force and JNC7, 59 children were hypertensive. Cortisol and cortisol/cortisone ratio were higher in hypertensive (p<0.001).

- No hyperaldosteronism was found. A positive linear correlation was observed between SBP and DBP with: BMI-SDS, HOMA-IR, cortisol/cortisone ratio and MMP-2, MMP-9 activities. However, correlations with SA, PRA and ARR were not significant.

- The variables associated with hypertension in the multivariate logistic model were: serum cortisol/cortisone ratio (OR: 4.73; CI=2.32 – 9.65), BMI-SDS (OR: 3.74; CI=1.91 – 7.32), MMP-9 (OR: 3.48; CI=1.79 – 6.78) and HOMA-IR (OR: 2.28; CI=1.10 – 4.38).

- The other variables we did not correlate with blood pressure.

CONCLUSIONS

Novel biomarkers such serum cortisol/cortisone ratio and MMP-9 activity emerged associated with paediatric hypertension. Further studies are needed to know the role of these markers in hypertensive patients.
