OBJECTIVES

Gonadotropin releasing hormone (GnRH) agonists are a common treatment modality for patients with central precocious puberty.

For investigation of short term & long term effects of GnRH agonists & antagonists on rats with precocious puberty, danazol-induced precocious puberty rats were used as an animal model to compare the effects of GnRH analogues and to assess combinations of treatment with agonistic and antagonistic GnRH analogues.

METHODS

5-d-old female Sprague-Dawley rats were subcutaneously injected with a single dose of 300 μg danazol. After vaginal opening, the rats were injected daily for 5 days with a combination of GnRH agonists (triptorelin) and antagonists (cetrorelix acetate). Serum levels of LH and FSH were obtained on d2, d5 and d15 of treatment.

Female Sprague-Dawley rats (5 days of age) → SC injected with a single dose of 300 μg danazol

RESULTS

Rats treated with danazol showed significant advancement in vaginal opening compared with wild type rats (p = 0.000, respectively). LH and FSH inhibition was strongest after 2-d treatment with antagonist alone (LH 1.07 ± 0.04 vs 1.25 ± 0.08 ng/mL in controls, p = 0.004; FSH 0.39 ± 0.03 vs 0.55 ± 0.09 ng/mL in controls, p = 0.006). Antagonist for 2-d followed with combined agonist/antagonist had the second lowest levels of LH and FSH, though not statistically significant (after 5-d treatment, LH 1.09 ± 0.05 vs 1.17 ± 0.04 ng/mL in controls, p = 0.33; FSH 0.46 ± 0.04 vs 0.47 ± 0.07 ng/mL in controls, p = 0.7). Agonist only group showed significant increase of LH and FSH after 5-d of treatment (LH 2.27 ± 0.08 vs 1.17 ± 0.04 ng/mL in controls, p < 0.0001; FSH 2.91 ± 0.65 versus 0.47 ± 0.07 ng/mL in controls, p = 0.0008)

CONCLUSIONS

Combination of GnRH agonist with antagonist, and especially treatment with antagonist alone seems to suppress gonadotropin levels most sufficiently. The danazol treated rat model proved to be a model of true precocious puberty; further related studies involving this animal model should be considered.
