Background
Central diabetes insipidus (CDI) is caused by deficiency of antidiuretic hormone (ADH). Patients with CDI are at risk for fluid balance disturbances, especially when there is impaired thirst perception or inability to access water freely. Blood sodium measurement gives a good reflection of the actual fluid balance but is generally not available in the home situation. For patients in which CDI is difficult to manage sodium measurement at home may be a good instrument for more self-reliance and possibly less emergency room visits and/or hospital admissions due to dysregulation of fluid balance

Aim: we describe a case of a boy with CDI and impaired thirst perception in whom the use of blood sodium, measured by the use of an i-STAT analyzer, has successfully led to more self-reliance and quality of life for him and his family

Case description
We describe a 5-year old boy with an optical pathway glioma with a complicated course of disease. As a consequence of his treatment he has psychomotor retardation, blindness and developed anterior hypopituitarism and CDI. He has an impaired thirst perception and is behaviorally focused on drinking. He was frequently admitted to the hospital because of dysregulation of his CDI as it was not possible to adequately adapt DDAVP dosage to his drinking behavior in the home situation. We found the i-STAT POCT analyzer (Abbott) to be a reliable system for sodium measurement at home. Expenses were covered by the health insurance company for a trial period (respectively 2 and 3 months).

During the trial period there was no need for extra ER visits in contrast to the period before home measurement. Also there haven been no clinical admissions due to dysregulation of fluid balance and consequently more comfort of the patient and his parents.

Conclusion
i-STAT sodium home measurement is an excellent example of personalized health care leading to more self-reliance and improvement of quality of life.
