# INTRODUCTION

Severe primary insulin-growth factor-1 (IGF1) deficiency (SPIGF1D) is a rare cause of growth delay.

Diagnostic criteria include age- and sexdependent low basal IGF1 levels (<2.5<sup>th</sup> percentile), height  $\leq$  -3SDS, absence of growth hormone (GH) deficiency and of any secondary causes of growth failure.

### AIM

- Report the growth pattern and pubertal status
- Identify the molecular causes of SPIGF1D
- Describe the growth response after 1-year of recombinant human IGF1 (rhIGF1) treatment in a young patient with ACAN mutation

# METHODS

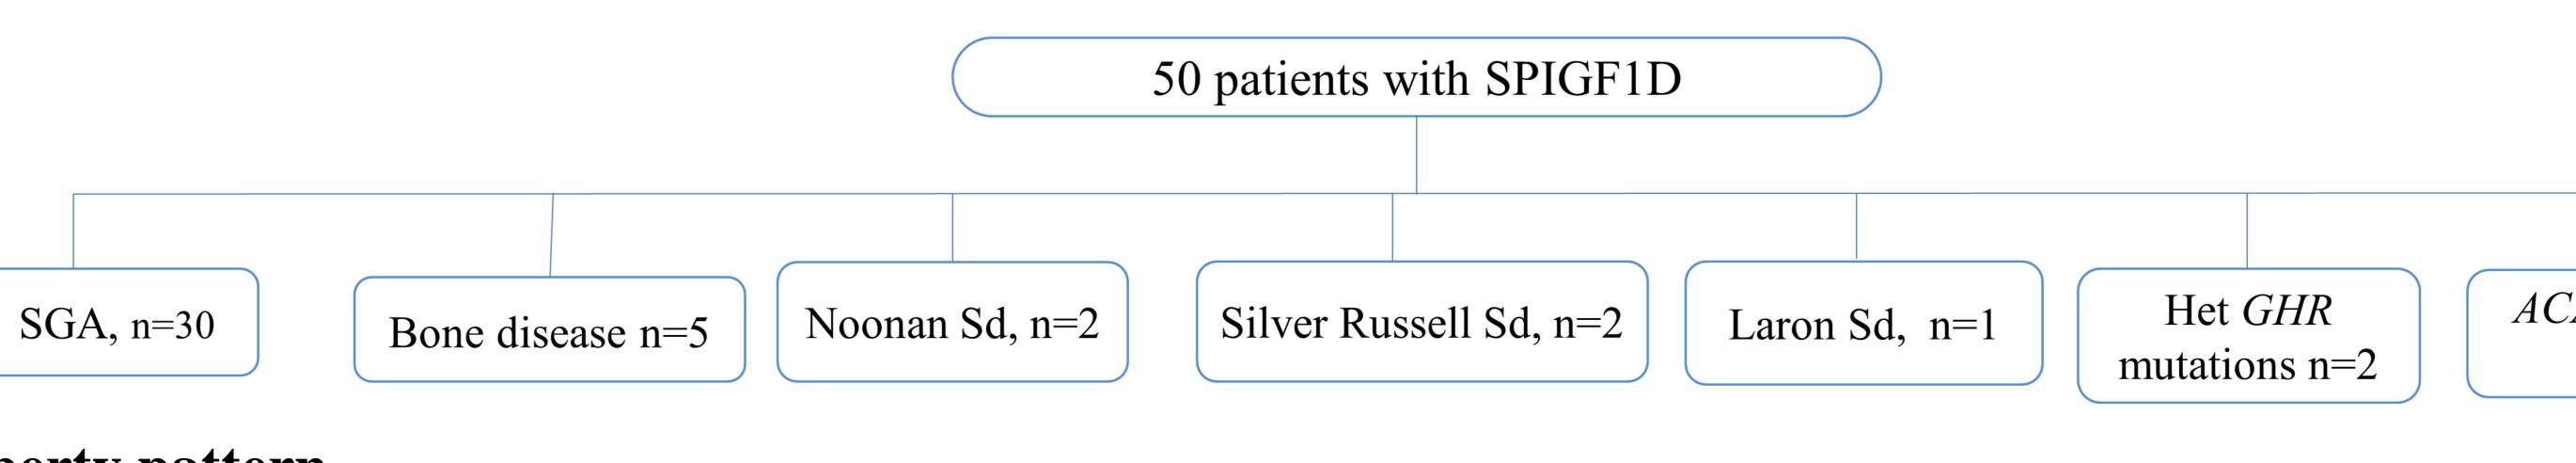

- Thirty patients (M/F:17/13, n=30) with SPIGF1D (*historical study cohort*) out of 2546 patients referred for growth failure to Paediatric Endocrinology Department of Necker Children's University Hospital, in Paris between 2004-2009 (Teissier et al, EJE, 2014).
- Twenty patients with SPIGF1D (new cohort, n=20) among patients referred with growth retardation between 2016-2020.
- Data were collected retrospectively concerning puberty and growth pattern
- Molecular studies are on going, based on a candidate gene approach or next-generation sequencing gene panel

ASSISTANCE DE PARIS

# RESULTS

### **Clinical and molecular characteristics of SPIGF1D patients**

### **Puberty pattern**

Pubertal onset: mean age for Tanner 2: 12.5 years (M, n=11) 12 years (F, n=8). Mean age of menarche was 13.6 years with regular menses.

Two boys had advanced evolutive central puberty, treated by GnRH agonist.

### Case report: A young patient with ACAN mutation treated with rhIGF1

Medical history:

A 5-year old girl was reffered to our clinic for growth failure. Born after a full term uneventful pregnancy, with SGA (BH: 47.5cm (4.5th p, BW: 3070g (14th p). Endocrine investigations showed SPIGF1D.

Molecular studies by NGS gene panel identified an heterozygous missense (p.Arg279Gln) mutation in the ACAN gene rhIGF1 started (0.04 mg/kg twice daily) at age of 6y (height: 104.5cm, -3SDS and after 1 year of treatment (0.12 mg/kg twice daily) very good response was documented, without any reported adverse effects.

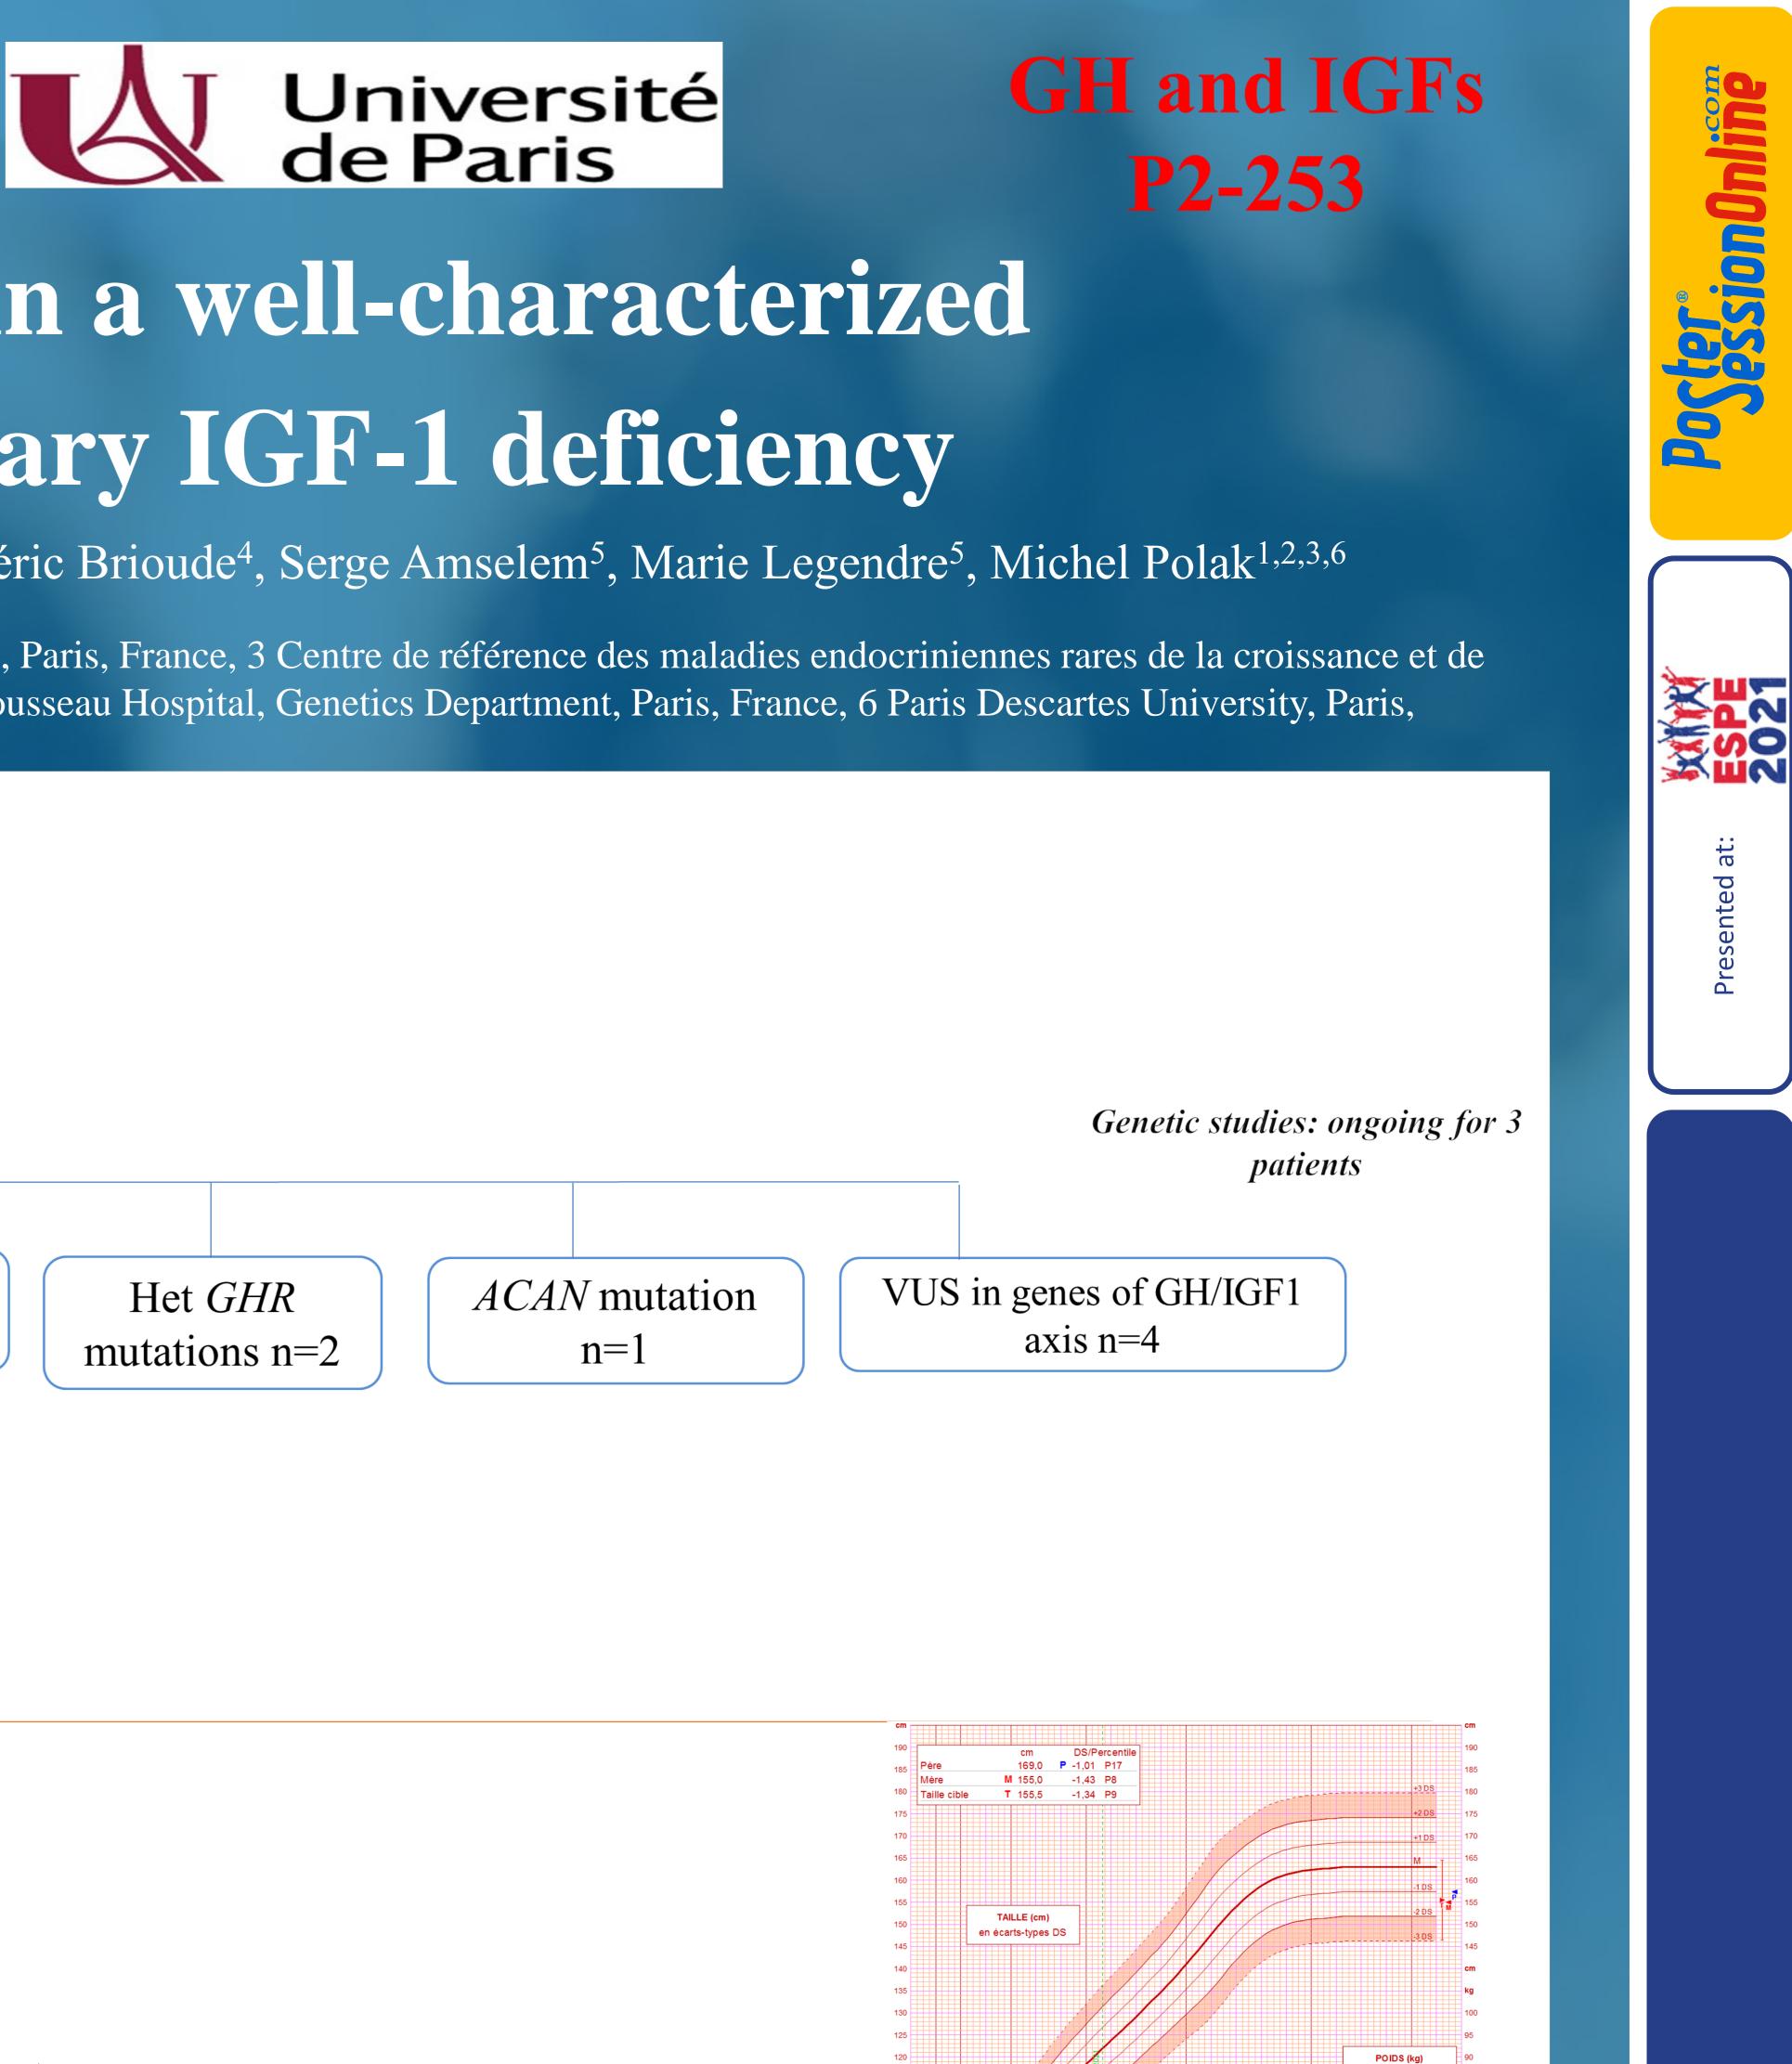

# CONCLUSIONS

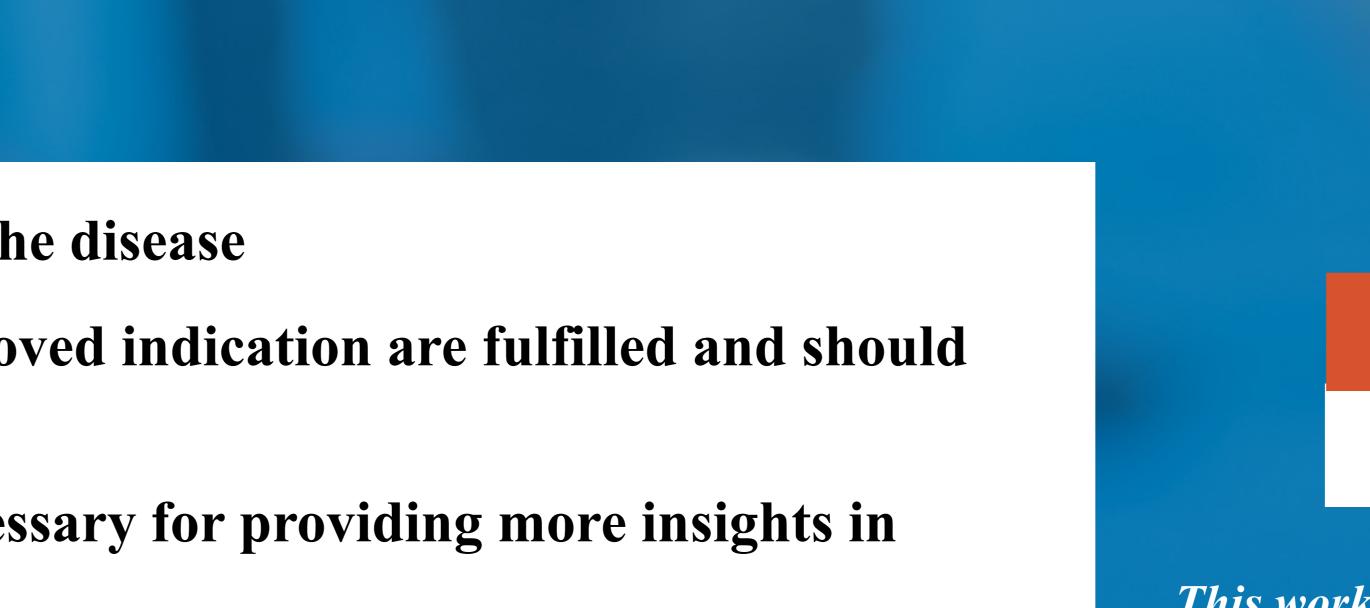

Genetic analysis reflect the heterogeneous spectrum of the disease

rhIGF1 is indicated if criteria for treatment in the approved indication are fulfilled and should not be delayed

Long-term follow-up and genetic investigations are necessary for providing more insights in the SPIGF1D management
